Wide $V_{\text{IN}}$ 1A Synchronous Buck Regulator

**ISL85410**

The ISL85410 is a 1A synchronous buck regulator with an input range of 3V to 36V. It provides an easy to use, high efficiency low BOM count solution for a variety of applications.

The ISL85410 integrates both high-side and low-side NMOS FETs and features a PFM mode for improved efficiency at light loads. This feature can be disabled if a forced PWM mode is desired. The part switches at a default frequency of 500kHz but may also be programmed using an external resistor from 300kHz to 2MHz. The ISL85410 has the ability to utilize internal or external compensation. By integrating both NMOS devices and providing internal configuration options, minimal external components are required, reducing BOM count and complexity of design.

With the wide $V_{\text{IN}}$ range and reduced BOM, the part provides an easy to implement design solution for a variety of applications while giving superior performance. It will provide a very robust design for high voltage industrial applications as well as an efficient solution for battery powered applications.

The part is available in a small Pb-free 4mmx3mm DFN plastic package with a full-range industrial temperature of -40°C to +125°C.

- AN1908, “ISL85410DEMO1Z, ISL85418DEMO1Z Wide $V_{\text{IN}}$ 1A, 800mA Synchronous Buck Regulator”

**Features**

- Wide input voltage range 3V to 36V
- Synchronous operation for high efficiency
- No compensation required
- Integrated high-side and low-side NMOS devices
- Selectable PFM or forced PWM mode at light loads
- Internal fixed (500kHz) or adjustable switching frequency 300kHz to 2MHz
- Continuous output current up to 1A
- Internal or external soft-start
- Minimal external components required
- Power-good and enable functions available

**Applications**

- Industrial control
- Medical devices
- Portable instrumentation
- Distributed power supplies
- Cloud infrastructure

Pin Descriptions

<table>
<thead>
<tr>
<th>PIN NUMBER</th>
<th>SYMBOL</th>
<th>PIN DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SS</td>
<td>The SS pin controls the soft-start ramp time of the output. A single capacitor from the SS pin to ground determines the output ramp rate. See “Soft-Start” on page 14 for soft-start details. If the SS pin is tied to VCC, an internal soft-start of 2ms will be used.</td>
</tr>
<tr>
<td>2</td>
<td>SYNC</td>
<td>Synchronization and light load operational mode selection input. Connect to logic high or VCC for PWM mode. Connect to logic low or ground for PFM mode. Logic ground enables the IC to automatically choose PFM or PWM operation. Connect to an external clock source for synchronization with positive edge trigger. Sync source must be higher than the programmed IC frequency. There is an internal 5MΩ pull-down resistor to prevent an undefined logic state if SYNC is left floating.</td>
</tr>
<tr>
<td>3</td>
<td>BOOT</td>
<td>Floating bootstrap supply pin for the power MOSFET gate driver. The bootstrap capacitor provides the necessary charge to turn on the internal N-Channel MOSFET. Connect an external 100nF capacitor from this pin to PHASE.</td>
</tr>
<tr>
<td>4</td>
<td>VIN</td>
<td>The input supply for the power stage of the regulator and the source for the internal linear bias regulator. Place a minimum of 4.7µF ceramic capacitance from VIN to GND and close to the IC for decoupling.</td>
</tr>
<tr>
<td>5</td>
<td>PHASE</td>
<td>Switch node output. It connects the switching FETs with the external output inductor.</td>
</tr>
<tr>
<td>6</td>
<td>PGND</td>
<td>Power ground connection. Connect directly to the system GND plane.</td>
</tr>
<tr>
<td>7</td>
<td>EN</td>
<td>Regulator enable input. The regulator and bias LDO are held off when the pin is pulled to ground. When the voltage on this pin rises above 1V, the chip is enabled. Connect this pin to VIN for automatic start-up. Do not connect EN pin to VCC since the LDO is controlled by EN voltage.</td>
</tr>
<tr>
<td>8</td>
<td>PG</td>
<td>Open-drain power-good output that is pulled to ground when the output voltage is below regulation limits or during the soft-start interval. There is an internal 5MΩ internal pull-up resistor.</td>
</tr>
<tr>
<td>9</td>
<td>VCC</td>
<td>Output of the internal 5V linear bias regulator. Decouple to PGND with a 1µF ceramic capacitor at the pin.</td>
</tr>
<tr>
<td>10</td>
<td>FB</td>
<td>Feedback pin for the regulator. FB is the inverting input to the voltage loop error amplifier. COMP is the output of the error amplifier. The output voltage is set by an external resistor divider connected to FB. In addition, the PWM regulator’s power-good and UVLO circuits use FB to monitor the regulator output voltage.</td>
</tr>
<tr>
<td>11</td>
<td>COMP</td>
<td>COMP is the output of the error amplifier. When it is tied to VCC, internal compensation is used. When only an RC network is connected from COMP to GND, external compensation is used. See &quot;Loop Compensation Design&quot; on page 17 for more details.</td>
</tr>
<tr>
<td>12</td>
<td>FS</td>
<td>Frequency selection pin. Tie to VCC for 500kHz switching frequency. Connect a resistor to GND for adjustable frequency from 300kHz to 2MHz.</td>
</tr>
<tr>
<td>EPAD</td>
<td>GND</td>
<td>Signal ground connections. Connect to application board GND plane with at least 5 vias. All voltage levels are measured with respect to this pin. The EPAD MUST NOT float.</td>
</tr>
</tbody>
</table>

NOTES:
1. Add ‘T’ suffix for Tape and Reel. Please refer to TB347 for details on reel specifications.
2. These Intersil Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.
3. For Moisture Sensitivity Level (MSL), please see device information page for ISL85410. For more information on MSL please see techbrief TB363.

Detailed Description
The ISL85410 combines a synchronous buck PWM controller with integrated power switches. The buck controller drives internal high-side and low-side N-channel MOSFETs to deliver load current up to 1A. The buck regulator can operate from an unregulated DC source, such as a battery, with a voltage ranging from +3V to +36V. An internal LDO provides bias to the low voltage portions of the IC.

Peak current mode control is utilized to simplify feedback loop compensation and reject input voltage variation. User selectable internal feedback loop compensation further simplifies design. The ISL85410 switches at a default 500kHz.

The buck regulator is equipped with an internal current sensing circuit and the peak current limit threshold is typically set at 1.5A.

Power-On Reset
The ISL85410 automatically initializes upon receipt of the input power supply and continually monitors the EN pin state. If EN is held below its logic rising threshold, the IC is held in shutdown and consumes typically 2µA from the VIN supply. If EN exceeds its logic rising threshold, the regulator will enable the bias LDO and begin to monitor the VCC pin voltage. When the VCC pin voltage clears its rising POR threshold, the controller will initialize the switching regulator circuits. If VCC never clears the rising POR threshold, the controller will not allow the switching regulator to operate. If VCC falls below its falling POR threshold while the switching regulator is operating, the switching regulator will be shut down until VCC returns.

Soft-Start
To avoid large in-rush current, VOUT is slowly increased at start-up to its final regulated value. Soft-start time is determined by the SS pin connection. If SS is pulled to VCC, an internal 2ms timer is selected for soft-start. For other soft-start times, simply connect a capacitor from SS to GND. In this case, a 5.5µA current pulls up the SS voltage and the FB pin will follow this ramp until it reaches the 600mV reference level. Soft-start time for this case is described by Equation 1:

\[ \text{Time} (\text{ms}) = \frac{C(nF)}{0.109} \]  

(EQ. 1)

Power-Good
PG is the open-drain output of a window comparator that continuously monitors the buck regulator output voltage via the FB pin. PG is actively held low when EN is low and during the buck regulator soft-start period. After the soft-start period completes, PG becomes high impedance provided the FB pin is within the range specified in the “Electrical Specifications” on page 7. Should FB exit the specified window, PG will be pulled low until FB returns. Over-temperature faults also force PG low until the fault condition is cleared by an attempt to soft-start. There is an internal 5MΩ internal pull-up resistor.

PWM Control Scheme
The ISL85410 employs peak current-mode pulse-width modulation (PWM) control for fast transient response and pulse-by-pulse current limiting, as shown in the “Functional Block Diagram” on page 5. The current loop consists of the current sensing circuit, slope compensation ramp, PWM comparator, oscillator and latch. Current sense trans-resistance is typically 500mV/A and slope compensation rate, Se, is typically 450mV/T where T is the switching cycle period. The control reference for the current loop comes from the error amplifier's output (VCOMP).

A PWM cycle begins when a clock pulse sets the PWM latch and the upper FET is turned on. Current begins to ramp up in the upper FET and inductor. This current is sensed (VCSA), converted to a voltage and summed with the slope compensation signal. This combined signal is compared to VCOMP and when the signal is equal to VCOMP, the latch is reset. Upon latch reset, the upper FET is turned off and the lower FET turned on allowing current to ramp down in the inductor. The lower FET will remain on until the clock initiates another PWM cycle. Figure 44 shows the typical operating waveforms during the PWM operation. The dotted lines illustrate the sum of the current sense and slope compensation signal.

Output voltage is regulated as the error amplifier varies VCOMP and thus output inductor current. The error amplifier is a transconductance type and its output (COMP) is terminated with a series RC network to GND. This termination is internal (150k/54pF) if the COMP pin is tied to VCC. Additionally, the transconductance for COMP = VCC is 50µA/V vs 230µA/V for external RC connection. Its noninverting input is internally connected to a 600mV reference voltage and its inverting input is connected to the output voltage via the FB pin and its associated divider network.
Light Load Operation

At light loads, converter efficiency may be improved by enabling variable frequency operation (PFM). Connecting the SYNC pin to GND will allow the controller to choose such operation automatically when the load current is low. Figure 43 shows the DCM operation. The IC enters the DCM mode of operation when 8 consecutive cycles of inductor current crossing zero are detected. This corresponds to a load current equal to 1/2 the peak-to-peak inductor ripple current and set by Equation 2:

\[ I_{OUT} = \frac{V_{OUT}(1 - D)}{2Lf_{SW}} \]  

(EQ. 2)

where \( D \) = duty cycle, \( f_{SW} \) = switching frequency, \( L \) = inductor value, \( I_{OUT} \) = output loading current, \( V_{OUT} \) = output voltage.

While operating in PFM mode, the regulator controls the output voltage with a simple comparator and pulsed FET current. A comparator signals the point at which FB is equal to the 600mV reference at which time the regulator begins providing pulses of current until FB is moved above the 600mV reference by 1%. The current pulses are approximately 300mA and are issued at a frequency equal to the converters programmed PWM operating frequency.

Due to the pulsed current nature of PFM mode, the converter can supply limited current to the load. Should load current rise beyond the limit, \( V_{OUT} \) will begin to decline. A second comparator signals an FB voltage 1% lower than the 600mV reference and forces the converter to return to PWM operation.

Output Voltage Selection

The regulator output voltage is easily programmed using an external resistor divider to scale \( V_{OUT} \) relative to the internal reference voltage. The scaled voltage is applied to the inverting input of the error amplifier; refer to Figure 45.

The output voltage programming resistor, \( R_3 \), depends on the value chosen for the feedback resistor, \( R_2 \), and the desired output voltage, \( V_{OUT} \), of the regulator. Equation 3 describes the relationship between \( V_{OUT} \) and resistor values.

\[ R_3 = \frac{R_2 \times 0.6V}{V_{OUT} - 0.6V} \]  

(EQ. 3)

If the desired output voltage is 0.6V, then \( R_3 \) is left unpopulated and \( R_2 \) is 0Ω.

Protection Features

The ISL85410 is protected from overcurrent, negative overcurrent and over-temperature. The protection circuits operate automatically.

Overcurrent Protection

During PWM on-time, current through the upper FET is monitored and compared to a nominal 1.5A peak overcurrent limit. In the event that current reaches the limit, the upper FET will be turned off until the next switching cycle. In this way, FET peak current is always well limited.

If the overcurrent condition persists for 17 sequential clock cycles, the regulator will begin its hiccup sequence. In this case, both FETs will be turned off and PG will be pulled low. This
condition will be maintained for 8 soft-start periods after which the regulator will attempt a normal soft-start.

Should the output fault persist, the regulator will repeat the hiccup sequence indefinitely. There is no danger even if the output is shorted during soft-start.

If $V_{OUT}$ is shorted very quickly, FB may collapse below $5/8$ths of its target value before 17 cycles of overcurrent are detected. The ISL85410 recognizes this condition and will begin to lower its switching frequency proportional to the FB pin voltage. This insures that under no circumstance (even with $V_{OUT}$ near 0V) will the inductor current run away.

**Negative Current Limit**

Should an external source somehow drive current into $V_{OUT}$, the controller will attempt to regulate $V_{OUT}$ by reversing its inductor current to absorb the externally sourced current. In the event that the external source is low impedance, current may be reversed to unacceptable levels and the controller will initiate its negative current limit protection. Similar to normal overcurrent, the negative current protection is realized by monitoring the current through the lower FET. When the valley point of the inductor current reaches negative current limit, the lower FET is turned off and the upper FET is forced on until current reaches the positive current limit. At this point the controller will turn off both FET's and wait for the positive current limit or an internal clock signal is issued. At this point, the lower FET is allowed to operate. Should the current again be pulled to the negative limit on the next cycle, the upper FET will again be forced on and current will be forced to $1/6$th of the positive current limit. At this point the controller will turn off both FET's and wait for COMP to indicate return to normal operation. During this time, the controller will apply a 100Ω load from PHASE to PGND and attempt to discharge the output. Negative current limit is a pulse-by-pulse style operation and recovery is automatic.

**Over-Temperature Protection**

Over-temperature protection limits maximum junction temperature in the ISL85410. When junction temperature ($T_J$) exceeds +150°C, both FETs are turned off and the controller waits for temperature to decrease by approximately 20°C. During this time PG is pulled low. When temperature is within an acceptable range, the controller will initiate a normal soft-start sequence. For continuous operation, the +125°C junction temperature rating should not be exceeded.

**Boot Undervoltage Protection**

If the boot capacitor voltage falls below 1.8V, the boot undervoltage protection circuit will turn on the lower FET for 400ns to recharge the capacitor. This operation may arise during long periods of no switching such as PFM no load situations. In PWM operation near dropout ($V_{IN}$ near $V_{OUT}$), the regulator may hold the upper FET on for multiple clock cycles. To prevent the boot capacitor from discharging, the lower FET is forced on for approximately 200ns every 10 clock cycles.

**Application Guidelines**

**Simplifying the Design**

While the ISL85410 offers user programmed options for most parameters, the easiest implementation with fewest components involves selecting internal settings for SS, COMP and FS. Table 1 on page 4 provides component value selections for a variety of output voltages and will allow the designer to implement solutions with a minimum of effort.

**Operating Frequency**

The ISL85410 operates at a default switching frequency of 500kHz if the FS pin is tied to VCC. Tie a resistor from the FS pin to GND to program the switching frequency from 300kHz to 2MHz, as shown in Equation 4.

$$R_{FS}[kΩ] = 108.75kΩ*(t – 0.2\mu s)/1\mu s$$ (EQ. 4)

Where:

- $t$ is the switching period in $\mu$s.

[FIGURE 46. $R_{FS}$ SELECTION vs $f_{SW}$]

**Synchronization Control**

The frequency of operation can be synchronized up to 2MHz by an external signal applied to the SYNC pin. The rising edge on the SYNC triggers the rising edge of PHASE. To properly sync, the external source must be at least 10% greater than the programmed free running IC frequency.

**Output Inductor Selection**

The inductor value determines the converter’s ripple current. Choosing an inductor current requires a somewhat arbitrary choice of ripple current, $\Delta I$. A reasonable starting point is 30% of total load current. The inductor value can then be calculated using Equation 5:

$$L = \frac{V_{IN} - V_{OUT}}{f_{SW} \times \Delta I} \times \frac{V_{OUT}}{V_{IN}}$$ (EQ. 5)

Increasing the value of inductance reduces the ripple current and thus, the ripple voltage. However, the larger inductance value may reduce the converter’s response time to a load transient. The inductor current rating should be such that it will not saturate in overcurrent conditions. For typical ISL85410 applications, inductor values generally lie in the 10µH to 47µH range. In general, higher $V_{OUT}$ will mean higher inductance.
Buck Regulator Output Capacitor Selection

An output capacitor is required to filter the inductor current. The current mode control loop allows the use of low ESR ceramic capacitors and thus supports very small circuit implementations on the PC board. Electrolytic and polymer capacitors may also be used.

While ceramic capacitors offer excellent overall performance and reliability, the actual in-circuit capacitance must be considered. Ceramic capacitors are rated using large peak-to-peak voltage swings and with no DC bias. In the DC/DC converter application, these conditions do not reflect reality. As a result, the actual capacitance may be considerably lower than the advertised value. Consult the manufacturers data sheet to determine the actual in-application capacitance. Most manufacturers publish capacitance vs DC bias so that this effect can be easily accommodated. The effects of AC voltage are not frequently published, but an assumption of ~20% further reduction will generally suffice. The result of these considerations may mean an effective capacitance 50% lower than nominal and this value should be used in all design calculations. Nonetheless, ceramic capacitors are a very good choice in many applications due to their reliability and extremely low ESR.

The following equations allow calculation of the required capacitance to meet a desired ripple voltage level. Additional capacitance may be used.

For the ceramic capacitors (low ESR):

\[ V_{OUT,ripple} = \frac{\Delta I}{8 \cdot f_{SW} \cdot C_{OUT}} \]  
(EQ. 6)

where \( \Delta I \) is the inductor’s peak-to-peak ripple current, \( f_{SW} \) is the switching frequency and \( C_{OUT} \) is the output capacitor.

If using electrolytic capacitors then:

\[ V_{OUT,ripple} = \Delta I \cdot ESR \]  
(EQ. 7)

Loop Compensation Design

When COMP is not connected to VCC, the COMP pin is active for external loop compensation. The ISL85410 uses constant frequency peak current mode control architecture to achieve a fast loop transient response. An accurate current sensing pilot device in parallel with the upper MOSFET is used for peak current control signal and overcurrent protection. The inductor is not considered as a state variable since its peak current is constant, and the system becomes a single order system. It is much easier to design a type II compensator to stabilize the loop than to implement voltage mode control. Peak current mode control has an inherent input voltage feed-forward function to achieve good line regulation. Figure 47 shows the small signal model of the synchronous buck regulator.

Figure 48 shows the type II compensator and its transfer function is expressed as shown in Equation 8:

\[ A_v(S) = \frac{V_{COMP}}{V_{FB}} = \frac{GM \cdot R_3}{(C_6 + C_7) \cdot (R_2 + R_3)} \cdot \frac{\left(1 + \frac{S}{\omega_{cz1}}\right) \left(1 + \frac{S}{\omega_{cz2}}\right)}{\left(1 + \frac{S}{\omega_{cp1}}\right) \left(1 + \frac{S}{\omega_{cp2}}\right)} \]  
(EQ. 8)

where,

\[ \omega_{cz1} = \frac{1}{R_6 C_6} \quad \omega_{cz2} = \frac{1}{R_2 C_2} \quad \omega_{cp1} = \frac{C_6 + C_7}{R_6 C_6 C_7} \quad \omega_{cp2} = \frac{R_2 + R_3}{C_3 R_2 R_3} \]

Compensator design goal:

High DC gain

Choose loop bandwidth \( f_c \) less than 100kHz

Gain margin: >10dB

Phase margin: >40°

The compensator design procedure is as follows:

The loop gain at crossover frequency of \( f_c \) has a unity gain. Therefore, the compensator resistance \( R_6 \) is determined by Equation 9.
Where $GM$ is the transconductance, $g_{m0}$ of the voltage error amplifier in each phase. Compensator capacitor $C_6$ is then given by Equation 10.

\[
C_6 = \frac{R_6}{R_6} \frac{V_o C_o}{I_o R_o} R_6 = \max(\frac{R_6 C_o}{R_6} \frac{1}{\pi f_{SW} R_6})
\]  
(EQ. 10)

Put one compensator pole at zero frequency to achieve high DC gain, and put another compensator pole at either ESR zero frequency or half switching frequency, whichever is lower in Equation 10. An optional zero can boost the phase margin. $\Omega_{CZ2}$ is a zero due to $R_2$ and $C_3$.

Put compensator zero 2 to 5 times $f_c$.

\[
C_3 = \frac{1}{\pi f_c R_2}
\]  
(EQ. 11)

Example: $V_{IN} = 12V$, $V_O = 5V$, $I_O = 1A$, $f_{SW} = 500kHz$, $R_2 = 90.9k\Omega$, $C_o = 22\mu F/5m\Omega$, $L = 39\mu H$, $f_c = 50kHz$, then compensator resistance $R_6$:

\[
R_6 = 22.75 \times 10^{-3} \cdot 50kHz \cdot 5V \cdot 22\mu F = 125.12k\Omega
\]  
(EQ. 12)

It is acceptable to use $124k\Omega$ as the closest standard value for $R_6$.

\[
C_6 = \frac{5V \cdot 22\mu F}{1A \cdot 124k\Omega} = 0.88nF
\]  
(EQ. 13)

\[
C_7 = \max(\frac{5m\Omega \cdot 22\mu F}{124k\Omega}) \frac{1}{\pi \cdot 500kHz \cdot 124k\Omega} = 0.88pF, 5.1pF
\]  
(EQ. 14)

It is also acceptable to use the closest standard values for $C_6$ and $C_7$. There is approximately $3pF$ parasitic capacitance from $V_{COMP}$ to GND; Therefore, $C_7$ is optional. Use $C_6 = 1500pF$ and $C_7 = OPEN$.

\[
C_3 = \frac{1}{\pi \cdot 50kHz \cdot 90.9k\Omega} = 70pF
\]  
(EQ. 15)

Use $C_3 = 68pF$. Note that $C_3$ may increase the loop bandwidth from previous estimated value. Figure 49 shows the simulated voltage loop gain. It is shown that it has a $75kHz$ loop bandwidth with a $61^\circ$ phase margin and $6dB$ gain margin. It may be more desirable to achieve an increased gain margin. This can be accomplished by lowering $R_6$ by 20% to 30%. In practice, ceramic capacitors have significant derating on voltage and temperature, depending on the type. Please refer to the ceramic capacitor datasheet for more details.
Layout Considerations

Proper layout of the power converter will minimize EMI and noise and insure first pass success of the design. PCB layouts are provided in multiple formats on the Intersil web site. In addition, Figure 50 will make clear the important points in PCB layout. In reality, PCB layout of the ISL85410 is quite simple.

A multi-layer printed circuit board with GND plane is recommended. Figure 50 shows the connections of the critical components in the converter. Note that capacitors $C_{IN}$ and $C_{OUT}$ could each represent multiple physical capacitors. The most critical connections are to tie the PGND pin to the package GND pad and then use vias to directly connect the GND pad to the system GND plane. This connection of the GND pad to system plane insures a low impedance path for all return current, as well as an excellent thermal path to dissipate heat. With this connection made, place the high frequency MLCC input capacitor near the VIN pin and use vias directly at the capacitor pad to tie the capacitor to the system GND plane.

The boot capacitor is easily placed on the PCB side opposite the controller IC and 2 vias directly connect the capacitor to BOOT and PHASE.

Place a 1µF MLCC near the VCC pin and directly connect its return with a via to the system GND plane.

Place the feedback divider close to the FB pin and do not route any feedback components near PHASE or BOOT. If external components are used for SS, COMP or FS the same advice applies.

About Intersil

Intersil Corporation is a leading provider of innovative power management and precision analog solutions. The company’s products address some of the largest markets within the industrial and infrastructure, mobile computing and high-end consumer markets.

For the most updated datasheet, application notes, related documentation and related parts, please see the respective product information page found at www.intersil.com.

You may report errors or suggestions for improving this datasheet by visiting www.intersil.com/ask.

Reliability reports are also available from our website at www.intersil.com/support.

For additional products, see www.intersil.com/en/products.html

Intersil products are manufactured, assembled and tested utilizing ISO9001 quality systems as noted in the quality certifications found at www.intersil.com/en/support/qualandreliability.html

Intersil products are sold by description only. Intersil Corporation reserves the right to make changes in circuit design, software and/or specifications at any time without notice. Accordingly, the reader is cautioned to verify that data sheets are current before placing orders. Information furnished by Intersil is believed to be accurate and reliable. However, no responsibility is assumed by Intersil or its subsidiaries for its use; nor for any infringements of patents or other rights of third parties which may result from its use. No license is granted by implication or otherwise under any patent or patent rights of Intersil or its subsidiaries.
